

Intra IUB Hackathon

ROUND Final Round	DURATION 4 Hours	GOAL Working Prototype
-----------------------------	----------------------------	----------------------------------

Build a small, complete, and safe AI system that helps a human review contracts.

The simplest reliable solution is better than an unnecessarily complex solution.

1. Background

Companies use contracts for many purposes, including:

- Hiring employees
- Buying software
- Working with vendors
- Making partnerships
- Paying for services

Contracts often contain important rules about payment, termination, privacy, ownership, and legal responsibility. Reading contracts takes time. Important risks can also be easy to miss. AI can help by finding important clauses and comparing them with a company's approved rules. However, the AI must not make up information or make a final legal decision.

Important

The system is an assistant. A human reviewer will always make the final decision.

2. Problem Statement

Build a simple AI-powered contract review assistant.

- The system should read a contract, find important clauses, compare them with the provided company standards, and show possible risks.
- The system must also show the exact text that supports its result.
- A human reviewer will make the final decision.

3. Your Goal

Your system should complete the following workflow:

1. Select a contract
2. Find important clauses
3. Find the matching company standard
4. Compare both texts
5. Show the risk level
6. Explain the reason
7. Show the evidence
8. Send for human review

Main Challenge

Build a small and complete contract review assistant that finds the right information, explains possible risks, shows evidence, and behaves safely when information is missing.

4. Required Clause Types

• Payment	• Termination
• Data protection	• Confidentiality
• Automatic renewal	• Intellectual property
• Limitation of liability	

Your system must support at least three of the following clause types. *The organizers may provide specific clause types for all teams.*

5. What the System Must Do

5.1 Read a Contract

The system should process a provided contract or contract text.

The organizers will provide clean sample data. Teams do not need to build advanced PDF scanning or OCR.

5.2 Find Important Clauses

The system should find clauses related to the selected risk categories.

Examples include a payment deadline, a termination rule, a privacy condition, or an automatic renewal clause.

5.3 Find the Company Standard

The organizers will provide approved company standards.

The system should retrieve the standard that matches the clause being reviewed.

5.4 Compare the Clause and the Standard

The system should compare what the contract says with what the company standard says.

It should then identify any important difference.

5.5 Show a Risk Level

The system should use these simple risk labels:

Low Risk	Medium Risk	High Risk	Not Enough Information
----------	-------------	-----------	------------------------

5.6 Explain the Result

The system should explain why it selected the risk level. The explanation should be simple and easy to understand.

5.7 Show Evidence

Every result must show:

- The contract clause
- The matching company standard
- The source of the information

The system should not give a risk result without evidence.

5.8 Handle Missing Information Safely

When the system cannot find enough information, it should say:

"Not enough information to make a reliable assessment."

It must not invent a clause, rule, or legal explanation.

5.9 Keep a Human in the Process

The system should clearly show that the result needs human review. You may add simple actions such as:

- Approve
- Reject
- Mark for review
- Add feedback

6. Example Output

Clause Type	Automatic Renewal
Risk Level	High Risk
Contract Clause	The agreement will automatically renew for another year unless cancelled 60 days before the end date.
Company Standard	Automatic renewal should require at least 30 days' notice.
Reason	The contract requires 60 days' notice, which is longer than the company standard.
Human Review	Required

7. Provided Materials

The organizers may provide:

- Sample contracts
- Contract excerpts
- Company-approved clause standards
- Test questions
- Expected clause categories
- Missing-information examples

The provided data will not contain real confidential information.

8. What You Need to Build

Your working prototype should include:

1. A way to select or upload a contract
2. Support for at least three clause types
3. Clause retrieval
4. Company-standard retrieval
5. Risk comparison
6. A risk level
7. A short explanation
8. Evidence display
9. A human-review step
10. One missing-information example

9. What You Need to Explain

During the presentation, explain:

- How your system works
- How you find the correct clause
- How you compare the clause with the standard
- How you prevent made-up answers
- How the system could handle more contracts in the future
- How private contracts could be protected
- What you would improve with more time

Scope Reminder

You do not need to build all production features during the four-hour round.

10. What Is Not Required

You are not required to build:

- A complete legal platform
- Advanced model fine-tuning
- Large-scale cloud infrastructure
- Complex authentication systems
- Full CI/CD pipelines
- Advanced monitoring dashboards
- OCR for scanned documents
- Real enterprise security systems
- A system that gives final legal advice

11. Technology Choice

You may use any technology you are comfortable with, including:

- A language model API
- Keyword search
- Vector search
- RAG
- Rule-based logic
- A simple agent workflow
- A combination of different methods

Engineering Principle

The simplest reliable solution is better than an unnecessarily complex solution.

12. Important Rules

1	Do not claim that the system gives legal advice.
2	Do not make up contract clauses or legal rules.
3	Show evidence for every risk result.
4	Use only the provided or approved information.
5	Mark uncertain results clearly.
6	Keep a human reviewer in the final decision process.

A successful submission is not the one with the most features. It is the one that works clearly, safely, and completely.
